ABSTRACT: A comprehensive review of the literature on echinoderm recorded in Thai waters was carried out in order to obtain the correct number of species found in this area. From the study, it was found that the total numbers of species are 381: 39 crinoids, 69 asteroids, 112 ophiuroids, 67 echinoids and 94 holothurians. All species presented and their distributions are tabulated herein. There are 14 type species of echinoderms inhabiting in Thai waters and four of them are endemic. The Andaman Sea has a greater diversity of echinoderms than those in the Gulf of Thailand. Most echinoderm recorded are of shallow waters while deep-water ones are remained relatively unexplored. Further study on echinoderms of shallow water should be done in term of monographic works and marine scientists should be encouraged in order to speed up the study on other aspects of these animals as well.

KEYWORDS: Echinoderms, biodiversity, Thailand, checklist.

INTRODUCTION

Echinoderms being common and conspicuous organisms of the seashore have attracted the attention of the naturalists since very early times. Hyman¹ saluted the echinoderms as a noble group especially designed to puzzle the zoologist. Exclusively marine, echinoderms are among the most common and widely spread groups of animals in the sea.¹ They are also among the most clearly defined of animal phyla. Members are characterized by the combination of basic pentamerous adult, a calcite skeleton and hydraulic tube feet or water vascular system.² Echinoderms include animals commonly known as feather star and sea lilies (Crinoidea); starfish or sea stars (Asteroidea); brittle and basket stars (Ophiuroidea); sea urchins, sand dollars and heart urchins (Echinoidea); and sea cucumbers (Holothuroidea). They play an important rule in marine ecosystems and some are economic marine animals.^{1,2,3}

Thailand, located in the South China Sea region and also in the Andaman Sea, plays an important role as the center of distribution of marine organisms and it may contain a very high number of species. The total coastline of Thailand is almost 2,600 kilometers, with over 300 islands. The coastlines consist of those areas along the Gulf of Thailand (Pacific Ocean) and the Andaman Sea (Indian Ocean) as well. However, many marine invertebrate fauna of Thailand are not comprehensively studied including echinoderms, and

the major expeditions have merely touched the fringes. It is the great opportunity for Thailand, when the Danish government and the Carlsberg foundation had supported the first Thai-Danish cooperation namely "The Danish Expedition to Siam 1899-1900". More than sixty Thai echinoderm species, including twelve new species were obtained.^{4,5,6} The following expedition was the Fifth Thai-Danish Marine Biology Expedition which had been carried out in Andaman Sea in 1969. In addition, The Danish Agency for Development Assistance (DANIDA) was the sponsor of the first training course and workshop on echinoderms in 1987, which contributed the great knowledge of echinoderms in Thailand.⁷ Over the century from the first expedition, we have still not reviewed and made the inventory of echinoderms in Thailand. This paper presents the history and comprehensive review of the literature on echinoderm recorded in Thai waters and further studies on this group of animals are still needed.

MATERIALS AND METHODS

Literature on echinoderms recorded in Thailand were collected and then the checklist of this group of animals was tabulated group by group. The confusion on scientific names had been updated taxonomically by following Rowe and Gates² and Lane, et al.⁸ Some unpublished data also included field survey; observation/collection by the authors. The data on type species; their localities and endemic species based

on the present state of their geographic distribution were also provided. For the purpose of the geographic distribution patterns, this inventory list is subdivided into two areas; the Gulf of Thailand (Pacific Ocean) and the Andaman Sea (Indian Ocean).

RESULTS AND DISCUSSION

Historic Reviews: The first recorded echinoderm for Thailand was mentioned on three echinoid species by Alexander Agassiz in "Revision of Echini" in 1872.⁶ In 1874, C.C.H. Bolau described the first new species of Thai echinoderm, *Anametalia sternaloides*, which had the type locality in the Gulf of Thailand, known as Gulf of Siam.² The first comprehensive expedition on echinoderms from Thailand was investigated by the cooperative Thai government and Danish government in 1899-1900. Supported by Danish government and Carlberg Foundation, Dr. Th. Mortensen, as the member of The Danish Expedition to Siam 1899-1900, spent three months collecting echinoderms along the eastern coast of the Gulf of Thailand.⁶ He reported a total of 17 species of regular echinoids including one new genus and one new species in 1903 and he also described 3 new species in 1904 and one new genus, *Clypeastroida* in 1948.^{6,9} The other echinoderms from this expedition had also been investigated by Koehler, who reported 29 species of ophiuroids including one new species.¹⁰ Heding⁴ described a new species of synaptid holothurian from Ko Kut and Heding and Panning⁵ reported 6 species of phyllophorid holothurians including 4 new species from the Gulf of Thailand. Mortensen also mentioned one diadematid echinoid from the Skeat Expedition, which had been explored along the southern coast of Thailand in 1901-1902.⁶ Döderlein¹¹ reported 6 species of Thai asteroids and he also described a new species of sea star from the Gulf of Thailand, which is now deposited in the Stockholm Museum.

Klinasak¹² was the first Thai scientist, who reported 49 species of Thai echinoderms from the NAGA Expedition and some of them were collected from the Gulf of Thailand and Andaman Sea. Sriyakorn⁷ reported 54 species from the Fifth Thai-Danish Marine Biology Expedition in Andaman Sea. Sanjindawong¹³ reported 17 holothurian species and 5 species were edible. In 1980s, there had been many works on Thai echinoderms. Waiyaniya¹⁴ reported 12 asteroids harvested by otter trawl from Pattaya area. She also reported 24 species from the Gulf of Thailand.^{15,16} Bussarawit and Rowe¹⁷ described a new species of Ophiocomid, *Ophiocoma similanensis* from the Andaman Sea. In 1987, Phuket Marine Biological center (PMBC) and DANIDA organized a training course and workshop in taxonomy, biology and ecology of echinoderms. The

result of the workshop showed 154 echinoderms recorded for Thailand.¹⁸ Putchakarn³ reported 56 echinoderm species from the eastern coast of Thailand and Putchakarn, et al.¹⁹ reported 33 echinoderm species from Ranong province on the Andaman Sea side. Putchakarn, et al.²⁰ reported 17 aspidochirotid holothurians from Lan and Phai Islands in Chonburi province, the Gulf of Thailand. Bussarawit and Thongtham²¹ listed 78 holothurians in Thailand. At present, there are two main institutes, which have been involved in the studies on echinoderms in Thailand. The first is PMBC, Department of Marine and Coastal Resources, Ministry of Natural Resources and Environment which collected approximately 160 species and most of them were from the Andaman Sea. Another is Institute of Marine Science (BIMS), Burapha University collected 175 species from both the Gulf of Thailand and Andaman Sea.

Inventory: A comprehensive review of the literature on echinoderms records for Thailand (as shown in Table 1) comprises 381 species in total; 39 crinoids, 69 asteroids, 112 ophiuroids, 67 echinoids and 94 holothurians. For comparison, Thai echinoderms are approximately 38 % of the South China Sea species⁸ and 33 % of Australian Waters.² Type specimens of 14 echinoderms found Thailand are consisted of one asteroid: *Astropecten fasciatus* Döderlein, 1926¹¹; two ophiuroids: *Ophiothrix abstinentis* Koehler, 1930¹⁰ and *Ophiocoma similanensis* Bussarawit & Rowe, 1985¹⁷; six echinoids: *Chaetodiadema granulatum* Mortensen, 1903⁶, *Paratrema doederleini* Mortensen, 1904⁶; *Temnotrema siamensis* (Mortensen, 1904)⁶, *Gymnechinus pulchellus* Mortensen, 1904⁶, *Fibularia angulipora* Mortensen, 1948⁹, and *Anametalia sternaloides* (Bolau, 1874)²; and five holothurians: *Phyllophorus* (*Phyllophorella*) *kohkutiensis* Heding & Panning, 1954⁵, *P. (Phyllophorella) robusta* Heding & Panning, 1954⁵, *Selenkiella malayense* Heding & Panning, 1954⁵, *S. siamense* Heding & Panning, 1954⁵, and *Opheodesoma lineata* Heding, 1928.⁴ One asteroid and three holothurians are considered to be endemic species of Thailand, namely *A. fasciatus*, *P. robusta*, *S. malayense* and *S. siamense*.

The distribution patterns of Thai echinoderms are as shown in Table 2. There are 93 species of echinoderms out of 190 species found only in the Gulf of Thailand and 191 species out of 288 species are found only Andaman Sea. And 97 species out of 381 species are found from the both areas. It should be noted that echinoderms from the Andaman Sea are more diverse than those in the Gulf of Thailand. The possible reasons for this might be that the habitats in the Andaman Sea are more diverse than those of the Gulf of Thailand and they are open water.

Although Thai echinoderm study has been done for

Table 1. Echinoderm species lists and distributions in Thailand.

Explanation of symbols: names of Thailand type species are bold; X = presence of species (bolded for type localities); * = specimens deposited at Institute of Marine Science, Burapha University; ** = specimens deposited at Phuket Marine Biological Center; A = field observation/collections of the author (1991-2000).

²² This included *Holothuria monocaria* (26) as a synonym of *H. (Thymiosycia) hilli* – see Rowe & Gates, 1995: 302.²³ According to taxonomic decision of Rowe & Gates, 1995: 324–326, it need to re-examine *Stichopus variegatus* specimens, especially from Andaman Sea.²⁴ This species was transferred from *Pentacta anceps* – see Rowe & Gates, 1995: 271–272.²⁵ This species was re-named from *Pentacta quadrangularis* – see Rowe & Gates, 1995: 272–273.²⁶ This species is probably misidentification – authors.²⁷ This species is a synonym of *P. (Phyllophorella) spiculata* Chang, 1935 – see Rowe & Gates, 1995: 312.

over a century, we have not yet completely known about their biodiversity. Up to the present, there is no monograph concerning Thai echinoderms. Most echinoderms of the former expedition were deposited in foreign museums. Since Thailand lacks funds and specialists, thus many specimens and types may have been overlooked. Some of the type species were lost and we cannot find other specimens in the type localities, especially ones in the Gulf of Thailand. One problem encountered at the present is that the marine environment changes rapidly in the Gulf of Thailand. Most of Thai echinoderms were obtained in shallow water (<30 meters depth). In recent years, PMBC have collected echinoderms from deep water of the Andaman Sea, but the result has not yet published. Most research works on Thai echinoderms are related to taxonomic works with little information on the ecology, life history and so on. Thus, it makes us lack other aspects of these animal's lives.

Need for Further Study on Biodiversity of Thai Echinoderms: As one can see from the historical account, the shallow water echinoderms are sufficient

for doing monographic works. The deep-water echinoderms should be encouraged for taxonomic study and others. According to the lack of biological and ecological information of echinoderms, it is important to encourage Thai marine scientists to speed up research work before it is too late to find echinoderm specimens for study.

ACKNOWLEDGEMENTS

This work was supported by Institute of Marine Science, Burapha University. We sincerely thank to Dr. Susumu Ohtsuka, Fisheries Laboratory, Hiroshima University, who kindly send us the request papers about echinoderms and Dr. Sabine Stohr, Swedish Museum of Natural History, who kindly send us a copy of Doderlein paper, Dr. Claude Massin for guiding on holothurians and Prof. Dr. Suebsin Sontirat assisted with English correction. Many thank for the staff of Phuket Marine Biological Center, Department of Marine and Coastal Resources, Ministry of Natural Resources and Environment for checking the specimens in the reference collection and our students for taxonomic works. Lastly, we would like to thank the staff of biodiversity research unit of Institute of Marine Science, Burapha University and our students of Burapha University for collecting specimens and providing the valuable discussion of this article.

Table 2. Distribution patterns of echinoderms from Thailand.

Taxa	Species distribution			Total
	Gulf of Thailand(GT)	Andaman Sea(AS)	GT & AS	
Crinoidea	4	33	2	39
Astroidea	17	37	15	69
Ophiuroidae	25	57	30	112
Echinoidea	17	25	25	67
Holothuroidea	30	39	25	94
Total	93	191	97	381
